

Process	Advantages	Disadvantages
Salt bath nitriding	<ul style="list-style-type: none"> • Rapid heating and processing • Ease of obtaining good nitrided layers on low carbon and low alloy steels in repeatable production 	<ul style="list-style-type: none"> • No in-process control • Processes limited to those steels, which can be heated to higher temperatures, without losing core hardness. • Short processes only • Requires thorough washing to remove salt residues which may cause corrosion • Health hazard and waste disposal problems
Ion nitriding	<ul style="list-style-type: none"> • Simple, mechanical masking of surfaces to be free of nitriding • Ease of surface activation through cathodic sputtering • Low temperature processes possible • Short saturation cycles 	<p>Problems with temperature measurement and uniformity</p> <p>Ease of overheating if not closely monitored</p> <p>Results sensitive to part geometry and arrangement in furnace retort</p> <p>Requires highly skilled and experienced operator</p>
Conventional gas nitriding	<ul style="list-style-type: none"> • Low temperature in comparison with carburizing • Simple control techniques 	<ul style="list-style-type: none"> • Controlling parameter: (ammonia dissociation rate) inadequate for control of layer properties • In many cases process produces a brittle white layer which requires removal • Masking requires copper plating or painting with protective paste • Stainless steels require special activation techniques
Controlled gas nitriding	<ul style="list-style-type: none"> • Ease of operation • Controlling parameter: (nitriding potential) has direct correlation with nitrogen concentration and properties • Predictable white layer thickness and phase composition • Excellent uniformity of layer, regardless of part geometry • No finish grinding required 	<ul style="list-style-type: none"> • Masking requires copper plating or painting with protective paste • Stainless steels require special activation techniques
